It is convenient to follow the Biometrical approach, which is based on correcting the unadjusted sum of squares (USS) by subtracting the correction factor (CF). Because all effects have been examined through frequencies, the USS can be obtained as the sum of the products of each genotype's frequency' and the square of its gene-effect. The CF in this case is the mean squared.

Evolutionary dynamics models in biometrical genetics supports QTL \times environment interactions. The process of development of quantitative trait locus (QTL) involves interactions between many factors, both environmental and genetic, in which many

Both pedigree structure and map information were incorporated into the QTL analysis by using a regression approach. The number of QTL detected for each trait and the number of effective factors calculated by using biometrical methods were of similar magnitude. Populations of IBLs were shown to be valuable for both marker mapping and QTL analysis.

A quantitative comparison between our model and empirical data requires information about the genetic architectures for hundreds of traits (see below for our analysis of expression QTLs). Nevertheless, the qualitative, non-monotonic predictions of our model (figure 1) may help to explain some well-known
