Choroidal fissure cysts may represent either neuroepithelial cysts (including neuroglial or gliopendymal cysts) 2, 6 or arachnoid cysts, although reports of pathologic confirmation are scant. Radiographic features. They are usually small and range around about 1-2 centimeters in diameter. Occasionally, larger cysts may be seen.

Most choroidal fissure cysts (CFC) are believed to be benign and asymptomatic and are usually an incidental MRI finding, when the latter is performed to exclude other diagnostic hypotheses. At MRI, CFC usually appear as focal CSF-intensity lesions which dilate the choroidal fissure of the temporal lobe. Therefore, MRI findings of the CSF-like cysts are important to recognize, so that they are not confused with other, more serious entities, such as intra-axial cystic tumours, or infectious or ...

The wall may be echogenic (due to surrounding choroid plexus). Some studies have suggested that the cysts should be at least 2.5 mm during the screening period of 13 to 21 weeks gestation and at least 2 mm from 22 to 38 weeks gestation for accurate diagnosis. This is to avoid confusing the surrounding choroid plexus heterogeneity as cysts.

Choroidal fissure cysts had a characteristic spindle shape on sagittal images. The other cysts were found in the temporal lobe (seven patients) or thalamus (one patient) and appeared parenchymal but situated close to the subarachnoid space. These lesions were round or ovoid.

The choroidal fissure is a space containing cerebrospinal fluid between the fimbria of the hippocampus and the diencephalon.1Choroidal fissure cysts are usually an incidental finding and often considered to be clinically benign, although some have been reported in association with medical and surgical morbidities.1,2However, the range of outcomes is broad, and there is little in the literature to assist in prediction of postnatal course from prenatal findings or to guide postnatal management.

This test uses a dye that lights up when exposed to infrared light. The resulting images show retinal blood vessels and the deeper, harder-to-see blood vessels behind the retina in a tissue called the choroid. Ultrasound. This test uses high-frequency sound waves (ultrasonography) to help view the retina and other structures in the eye.

A choroid cyst is a small buildup of fluid in the choroid plexus, a structure in the brain which produces cerebrospinal fluid (CSF). Choroid cysts are most commonly identified as an ultrasound finding, and are in fact not uncommon, being seen in around one to three percent of fetuses. Adults can sometimes also have a choroid cyst, and be entirely unaware of it, although it will show up in detailed imaging studies of the brain as a small bubble of fluid.

What is a Choroid Cyst? (with pictures)

The choroid fissure cysts are CSF filled and mostly considered neuroepithelial or arachnoid type [1-4]. Neuroepithelial cysts are lined by epithelium with or without basement membrane. Arachnoid cysts on the other hand are not lined by epithelium and are formed between layers of arachnoid or between dura. [1]

They are the most common type of intraventricular cyst. The brain contains pockets or spaces called ventricles with a spongy layer of cells and blood vessels called the choroid plexus. This is in the middle of the fetal brain. The choroid plexus has the important function of producing cerebrospinal fluid. The fluid produced by the cells of the choroid plexus fills the ventricles and then flows around the brain and the spinal cord to provide a cushion of fluid around these structures.

Choroid plexus cyst - Wikipedia

A choroid plexus carcinoma begins near the brain tissue that secretes cerebrospinal fluid. A noncancerous tumor of this area is called a choroid plexus papilloma. As the tumor grows, it can affect the function of nearby structures in the brain, causing excess fluid in the brain (hydrocephalus), irritability, nausea or vomiting, and headaches.

What are choroid plexus cysts? The choroid plexus is the part of the brain that makes cerebrospinal fluid, the fluid that normally bathes and protects the brain and spinal column. In about 1 to 2 percent of normal babies - 1 out of 50 to 100 - a tiny bubble of fluid is pinched off as the choroid plexus forms.

These are cysts that are found in the choroidal fissure - an area of the brain slightly toward the center, on the "inside" of the temporal lobe. These cysts are general small areas that are filled with fluid, and generally are seen incidentally on scanning of the brain.

The differential diagnosis of cysts located at the level of the choroidal fissure consists mainly of arachnoid or neuroepithelial cysts; however, cystic neoplasm, (epi-) dermoid cysts, and parasitic cysts are possible. Focal temporal lobe atrophy could lead to enlargement of the choroidal fissure simulating a cyst (19).
