Computer Architecture: Parallel Processing Basics

Parallel Processing and Data Transfer Modes in a Computer System Instead of processing each instruction sequentially, a parallel processing system provides concurrent data processing to increase the execution time. In this the system may have two or more ALU's and should be able to execute two or more instructions at the same time.

Parallel Computer Architecture - Models - Tutorialspoint

Parallel processing is a method in computing of running two or more processors (CPUs) to handle separate parts of an overall task. Breaking up different parts of a task among multiple processors will help reduce the amount of time to run a program.

What is Parallel Processing?

The book is intended as a text to support two semesters of courses in computer architecture at the college senior and graduate levels. There are excellent problems for students at the end of each chapter. The authors have divided the use of computers into the following four levels of sophistication: data processing, information processing, knowledge processing, and intelligence processing.

Parallel computers can be roughly classified according to the level at which the hardware supports parallelism, with multi-coreand multi-processorcomputers having multiple processing elementswithin a single machine, while clusters, MPPs, and gridsuse multiple computers to work on the same task.

Parallel computing - Wikipedia

Pipelining is joining multiple processing elements one after another to have a first-in-first-out style assembly line. Below is an example of $y = \sqrt{(x+1)*5}$ pipeline. Since each processing element (+1 or *5 or sqrt) works concurrently with others, it is also an example of parallelism. Parallelism is not pipelining but pipelining is parallel.
